1 Cardiac surgery is an effective, evidence-based clinical practice built on decades of  
 2 research spanning from basic science to rigorous large animal studies and randomized  
 3 controlled trials (RCTs) in patients. This translational approach has benefited patients  
 4 enormously<sup>1</sup>. More recently, we are witnessing a surge of different research methods from  
 5 bench-based simulation to overnight observational studies from registries and meta-  
 6 analysis that are raising questions and debates<sup>2</sup>. Concomitantly, in the era of innovation,  
 7 we witness a crisis in research reproducibility<sup>3</sup>, limited reporting of registered RCTs<sup>4</sup> and  
 8 a call to re-surface rigorous large animal research<sup>5</sup>. One is left wondering if these are signs  
 9 of a perfect storm. At these new times, the typical cardiac surgeon looks like a passive  
 10 passenger on the boat of innovation, struggling to keep the rudder straight while sailing  
 11 across the troubled waters of intellectual property, commercialization, conflict of interests,  
 12 harm<sup>6</sup> lack of evidence<sup>7</sup>, visibility, patient interest and evidence-based medicine. Who is  
 13 who in this storm? Paulsen and colleagues<sup>8</sup> have reported a bench-based model using a 3D-  
 14 printed heart simulator designed to test the long-term efficacy of two routinely used aortic  
 15 conduits for valve sparing procedures. This is despite thousands of patients have already  
 16 received these two conduits. The novelty of this report is that it tries to address an important  
 17 clinical question on the long-term durability of the conduits using a bench-based simulator.  
 18 The simulator is ingenious, modelling physiological waveforms and mechanical activities  
 19 of the heart. Porcine aortic root/valves were sutured in the two conduits followed by  
 20 implanting silicone tubes as mock coronary buttons. A long shot. At first look, few  
 21 conflicting questions come to mind: is this simulator reliable? Can it really predict long-  
 22 term durability by running for few hours? Where is the rigorous confirmatory trial in large  
 23 animals? Yet, we must respect this methodological approach as modern computational

24 modelling has been shown to be effective in predicting health outcome<sup>9</sup>. Based on the  
25 evidence arising from this simulation, the authors conclude that while the Valsalva Graft  
26 accurately reflect the aortic root geometry longitudinally, its radial displacement of the  
27 valve commissures triggers abnormal forces on the leaflets affecting their long-term  
28 durability. A strong conclusion, with not a single patient operated and not a drop of blood  
29 lost! With the only variable in this simulator being the type of conduit used, it might be  
30 that the highlighted difference is genuine. Who knows? In a traditional translational  
31 research pathway, this would trigger an immediate need for in-vivo validation in a relevant  
32 large animal model. However, the simulation has several limitations. The whole system  
33 looks too artificial as opposed to a typical in-vivo model. The lack of vascular elasticity in  
34 the system is an issue. Sub-optimal surgical expertise and/or mismatch between variable  
35 sizes of porcine valve used and the fixed diameter of the conduits selected might have  
36 affected the radial displacement of the leaflets. Finally, the simulation was conducted with  
37 normal saline solution and not with blood, using a fluid with different viscosity, hence  
38 affecting dynamics. These are the practical immediate criticisms that we can raise.  
39 Translational large animal models with advanced longitudinal in-vivo imaging would  
40 provide confirmatory knowledge of the pathophysiological, mechanistic and dynamic  
41 issues associated by this study with the Valsalva Graft surgical procedure. This, in turn,  
42 would have more robust implications on the clinical scenario, possibly warranting a call  
43 for a comparative RCT? The study by Paulsen and colleagues<sup>8</sup> also highlights that  
44 undertaking isolated bench-based simulation, no matter how good it can be, does not help  
45 much in moving the field forward. This is because real translation occurs across a pipeline  
46 in which bench simulation represents only the first step. This illustrates the key learning

47 point that bench-based modelling needs to go hand-to-hand with advanced in-vivo  
48 preclinical validation in relevant models<sup>10</sup>, to facilitate translation to bedside. Translating  
49 valuable basic science into patients requires time, funding, appropriate surgical skills,  
50 translational biomedical knowledge and high experimental reproducibility. A gap in  
51 translation seems to be the main limitation of this process. Rigorous in-vivo validation in  
52 relevant preclinical models may represent an effective way to bridge the gap between  
53 bench-based science and bed side across the storm. Like a bridge over troubled waters.
